

The nbaseprt package

Harald Harders
h.harders@tu-bs.de

Version v0.11, 2004/12/14; printed July 11, 2005

Abstract

This package prints integer numbers in different bases (octal, decimal, hexadecimal, binary) similarly to the `numprint` package. But here, the number of digits within one group depends on the base.

This version of `nbaseprt.sty` is a BETA VERSION. The main command `\nbaseprint` will stay stable but all configuration commands and the output of `\nbaseprint` may change in future. Please give me feedback what can be improved and if the abbreviations for the different number bases are correct.

1 Load the package

To use this package place

```
\usepackage{nbaseprt}
```

in the preamble of your document. The `nbaseprt` package calls the `numprint` package and parses all package options to it. Please read the documentation for the `numprint` package for details. If you want to use both the `numprint` and the `nbaseprt` package either load `numprint` first given all options, e.g.,

```
\usepackage[autolanguage,nosepfour]{numprint}  
\usepackage{nbaseprt}
```

or only load the `nbaseprt` package, giving it the options for `numprint`:

```
\usepackage[autolanguage,nosepfour]{nbaseprt}
```

2 Print numbers

`\nbaseprint` Numbers are printed using the `\nbaseprint{<number>}` command. Which number base is used is determined by parsing the `<number>`.

The type can be given by preceding the number by “0x”, “0o”, “0d”, or “0b” (or the uppercase characters) for hexadecimal, octal, decimal, or binary numbers, respectively. For example,

```
$\nbaseprint{0x1A0E3F}$, $\nbaseprint{0o377377}$,  
$\nbaseprint{0d192314}$, $\nbaseprint{0b11010110}$
```

Alternatively, hexadecimal and octal numbers can be given by appending “h”, “H”, “o”, or “O”:

```
$\nbaseprint{1A0E3Fh}$, $\nbaseprint{377377o}$
```

If neither is given, the number defaults to decimal.

The format of the printed numbers is similar to the possible input formats. By default, the numbers are preceded by “0x”, “0o”, “0d”, or “0b”, e.g.

```
0x 1A 0E 3F, 0o 377 377, 0d 192 314, 0b 1101 0110
```

`\nbaseposttext` You can change this by using `\nbaseposttext`. This leads to

```
1A 0E 3F h, 377 377 o, 192 314 d, 1101 0110 b
```

`\nbasepretext` You can switch back to the default behaviour using `\nbasepretext` or by using `\nbaseposttext` inside a group.

If you want to print negative numbers the sign may be written before or after “0x”, “0o”, “0d”, or “0b”. Some examples:

```
$\nbaseprint{-0x1A0E3F}$, $\nbaseprint{0o-377377}$,  
$\nbaseprint{0d+-192314}$, $\nbaseprint{0b\pm 11010110}$
```

which lead to

```
0x -1A 0E 3F, 0o -377 377, 0d ±192 314, 0b ±1101 0110
```

In the printout, the sign always is written after the base-specific string. (is this correct?)

3 Customization

3.1 Padding a number on the left side

`\nplpadding` Sometimes it is desirable to have a number of a fixed length with the missing digits filled with a character (mostly the character “0”, so this is the default). This can be achieved calling `\nplpadding[⟨character⟩]{⟨digits⟩}` borrowed from the `numprint` package. For example,

```
\nplpadding{6}%  
$\nbaseprint{0xA03E}$, $\nbaseprint{0o1234}$
```

leads to “0x00 A0 3E, 0o001 234”

`\npnolpadding` switches padding off.

4 International support

`nbaseprt` uses the thousand separator from `numprint`. Since this package uses the German “\,” by default `nbaseprt` does this, too. Using the package option `autolanguage` this can be fixed. If you are using this option without the `babel` package the settings are switched to English at `\begin{document}`: separator “,”. If using `babel` the separator is changed automatically when switching to a supported language.

If you do not want to use the `autolanguage` option you may use the `numprint` command `\npthousandsep` command to change the separator.

5 Print aligned numbers in tabulars

Sorry, not programmed, yet.

A Lists of options and commands

This section contains lists of all package options resp. available commands. Items that belong together and may be exclusive are printed in groups together.

A.1 Package options

`nbaseprt` supports all options of the `numprint` package. In this list, only the ones that are new or have a different meaning are listed.

The default values are marked by *.

<code>np</code>	Define the shortcuts <code>\np</code> for <code>\numprint</code> and <code>\nbp</code> for <code>\nbaseprint</code> .
-----------------	---

A.2 Commands

Commands that begin with `\np` are borrowed from `numprint`. Here, the new commands and `numprint` commands that have a special meaning for `nbaseprt` are listed here.

<code>\npaddplus</code>	Add a plus to a number without a sign.
<code>\npnoaddplus</code>	Don't do that.
<code>\nbp</code>	Shortcut for <code>\nbaseprint</code> (only available with package option <code>np</code>).
<code>\nbaseprint</code>	Typesets a number (the package's main command).
<code>\npthousandsep</code>	Change the separator between the digit groups.
<code>\nplpadding</code>	Declare up to how many digits the number will be padded at the lefthand side.
<code>\npnolpadding</code>	Switch off padding.
<code>\nbaserpretext</code>	Switches on to precede the number by "ox", "oo", or "od".
<code>\nbaserposttext</code>	Switches on to append "h", "o", or nothing to the number.

B To do

- Add table support.
- Better customization for the pre and the post text.
- Parse the argument for invalid numbers.
- Proof output format of numbers.

C The implementation

Heading of the package:

```

1 \NeedsTeXFormat{LaTeX2e}
2 \ProvidesPackage{nbaseprt}
3 [2004/12/14 v0.11 Print numbers with numerical bases (HH)]

```

Warning, that this is a beta version.

```

4 \typeout{^^J*****}
